Investigating Human-Automation Interaction and Human Error in the Locomotive Cab

Angelia Sebok

This work was supported by the FRA under contract
DTFR5312D0006L, TPOC: Michael Jones

- Automated systems are being developed and introduced into the locomotive cab.
- Lessons learned from aviation indicate that automation can help – or hurt – human and system performance.
- This work was performed to investigate human error potential in the locomotive cab when using different automated systems.
- One other key point: human performance researchers benefit from getting into the operational environment, and seeing how operators work in reality. But that's not always possible.

Performed analyses to investigate human error potential:

- *Walkthroughs in CTIL scenarios using automation*
- Modeling analyses using the Locomotive Cab Analysis Tool
- Fault tree analyses of actions and error probabilities
- Noticing – Salience Expectancy Effort and Value modeling predictions

Locomotive cab automation:

- Positive Train Control (Electronic Train Management System)
- Trip Optimizer

Human Error Evaluation

Performed at the Cab Technology Integration Laboratory (Volpe)

- 3 professional engineers participated in 3 scenarios on a simulated 17-mile run.
- Run 1: Training and familiarization / manual mode.
Run 2: Low workload, automated mode.
Run 3: High workload, automated mode. (one engineer did this twice)
- Collected human performance data, operator actions, and simulated train data

Manual

- 17-mile segment of track
- Speed restrictions and a quiet zone
- Manual horn and bell control

Automation (PTC or TO) – Low Workload

- Same segment of track, same speed restrictions, etc.
- PTC or TO engaged

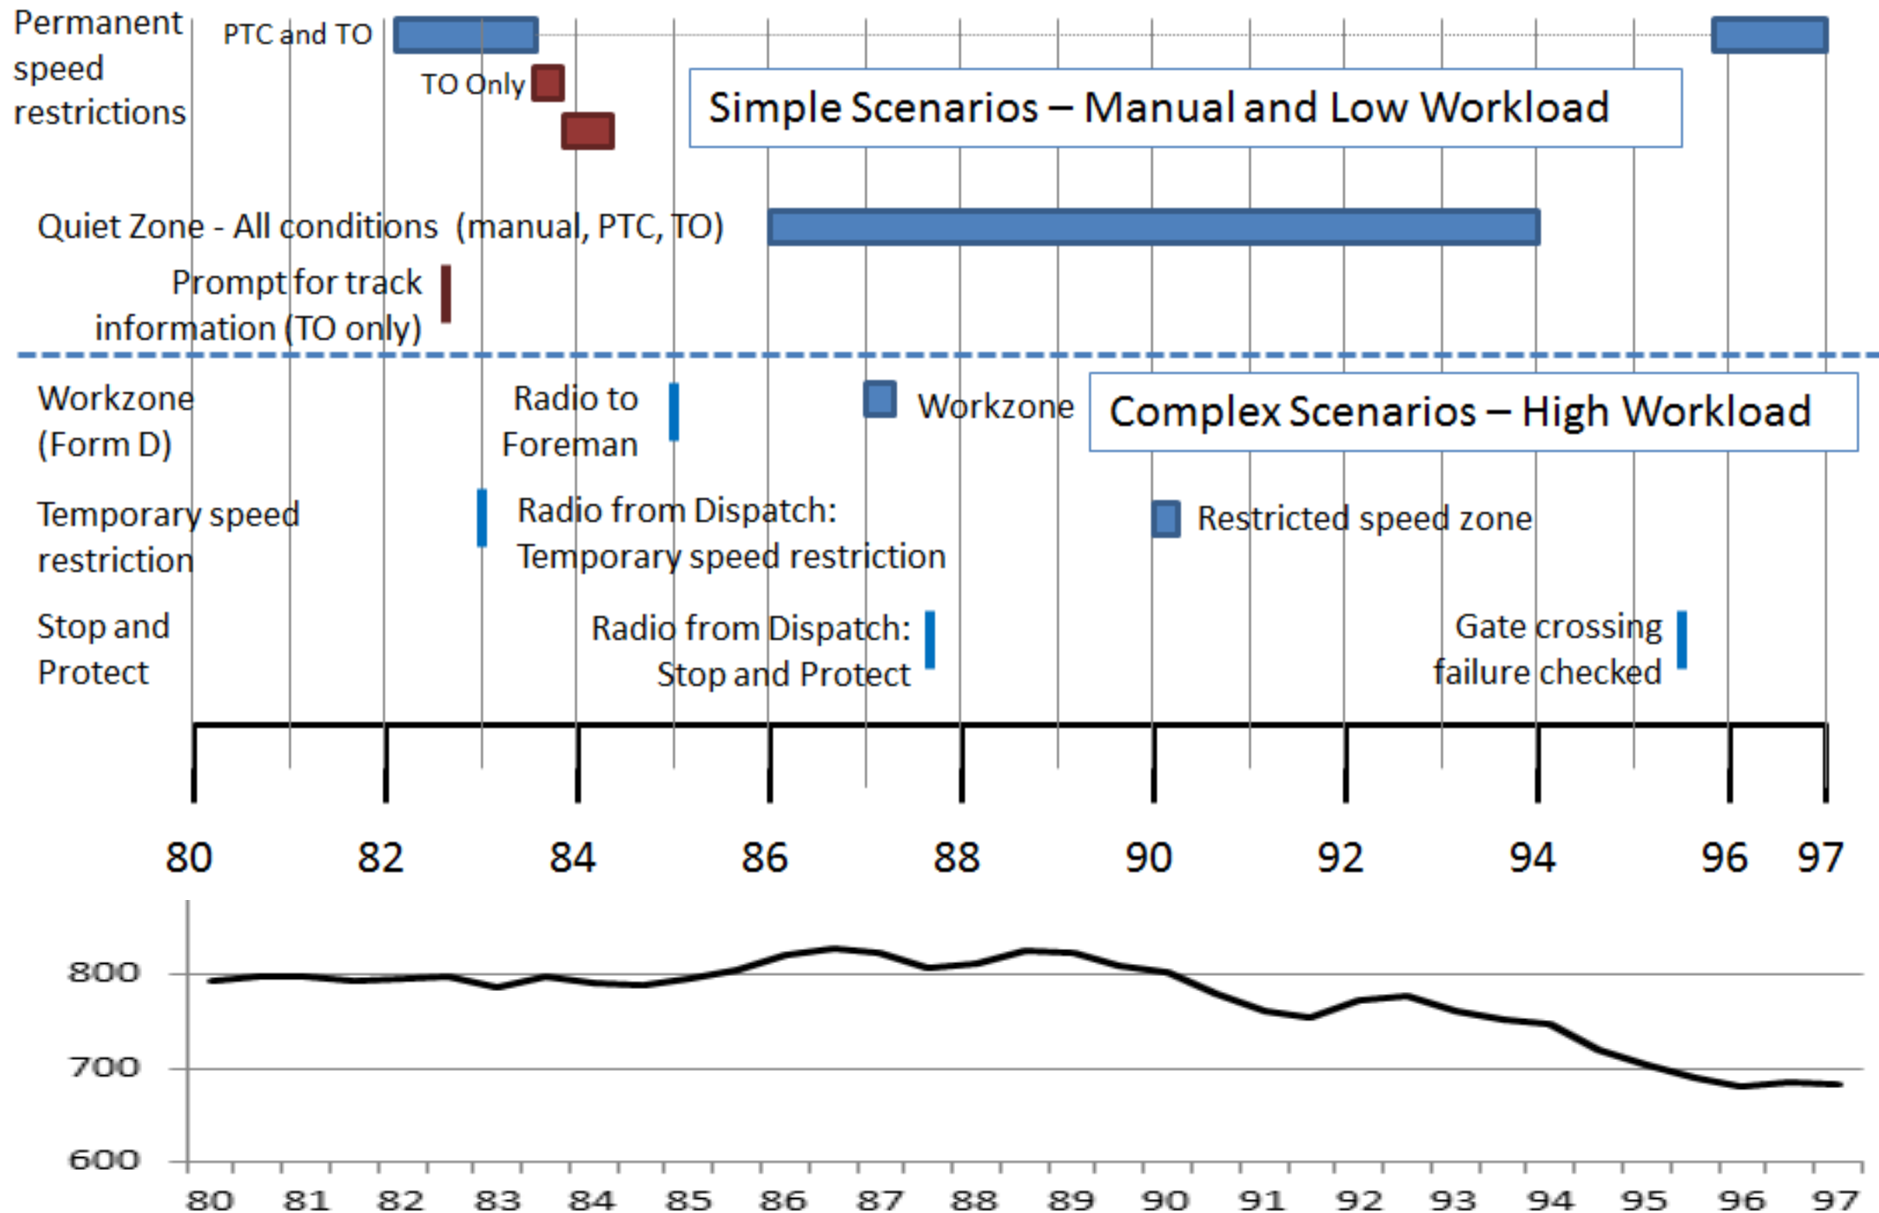

Automation – High Workload

- Same segment of track, same speed restrictions, etc.
- PTC or TO engaged
- Three extra events: A workzone, a temporary speed restriction, and a stop-and-protect at a grade crossing.
- Two of the three events were announced by the dispatcher during the run.

Scenarios, Events, and Track Profile

CTIL Human Error in HAI Evaluation

Short Summary of Results

- Three errors noted (two in the high workload condition)
 - Failure to notice TO request for information and switch to idle mode
 - Failure to stop before the grade crossing for the stop and protect condition
 - Sustained overspeed by 15 mph

Trip Optimizer Changes

Failure to Stop Before Grade Crossing

- One error (four opportunities) observed
- Overshot the grade crossing by 370 feet
- Did not anticipate the long downhill grade
- Visual representation of the grade was shown, and conductor reminded of the stop and protect

Overspeed

- Overspeed occurred in a 1.2 mile section at the end of a run
 - The speed restriction was for 45 mph
 - Actual average speed was 58.4 mph (max 63.3 mph)
- Stated an incorrect understanding of the speed restriction
- The indications did not trigger recognition of the overspeed.

- Identified errors that could occur when interacting with automation
 - Not noticing a system change
 - Lack of mode awareness
 - Distractions can have a negative impact
- The errors that we found in the CTIL were similar to operating experiences with automation
- Found concerns to investigate further in a human-in-the-loop experiment

CTIL provides an excellent resource for gaining insights into actual operations and evaluating responses to off-nominal conditions
